Interplay of hydrophobic and electrostatic effects in solvation of methylated cyclodextrin in aqueous solution: A molecular dynamics simulation study. The solvation of methylated cyclodextrin (mCD) has been studied in an aqueous environment using the molecular dynamics (MD) simulation technique. The hydrogen bonding properties of mCD have been examined in an aqueous solution to understand the hydrophobic effect of mCD in this environment. A comparison of the ability of mCD and normal cyclodextrin (nCD) to stabilize the aqueous environment around hydrophilic residues has been carried out. It has been observed that the substitution of hydroxyl groups by methyl groups reduces the ability of nCD to stabilize the aqueous environment by forming favorable hydrogen bonds. Both nCD and mCD are capable of providing favorable interactions in the aqueous environment through a combination of favorable electrostatic and hydrophobic interactions. The results also show that the solvation of mCD takes place in two stages. The molecular dynamics simulation results suggest that the first stage of solvation is associated with the preorganization of the aqueous environment, while the second stage of solvation involves the orientation of the methylated hydroxyl groups to provide favorable interactions with the water molecules.

In the dying days of the 2008 campaign, Hillary Clinton's campaign stumbled onto a piece of campaign gold — a poll that showed that Americans, contrary to what the pundits were saying, actually thought she was more likable than her opponent. The same poll, by the way, showed that her image as a leader was, in fact, a weak point, but the poll also showed that she had overwhelming support from
